

Learning goals

- Analyse stakeholders.
- Distinguish functional and non-functional requirements.
- Recognise ambiguity and unsupported requirements.
- Define scope.
- Develop user stories and acceptance criteria.
- Critique AI-generated requirements.

Activity 1 - Stakeholder Map

Stakeholder	Need	Potential conflict
Reception staff	Efficiently find information and create, update, or cancel appointments for patients.	Speed and convenience may conflict with validation needed to prevent incorrect or duplicate records.
Practitioners	Schedules and appointment statuses that are accurate.	Access to patient information may conflict with privacy and access restrictions
Patient	Personal information, appointments, and history.	Patient preferences may conflict with practitioner availability or clinic procedures.
Management	Maintainable system that reduces duplicate bookings and inconsistent records	Broader features may increase cost and make maintenance harder.
Developers and testers	Clear, testable requirements and maintainable business logic.	Technical quality work may require more time than stakeholders expect.

Activity 2 - Functional or Non-Functional?

- ☐ Functional The system shall allow staff to cancel an appointment.
- ☐ Non-functional The system should remain responsive for the course-scale dataset.
- ☐ Functional The system shall retain cancelled appointments.
- ☐ Non-functional Core business logic should be independently testable.
- ☐ Functional The system shall search for a patient by ID.

Activity 3 - Repair Ambiguous Requirements

The system should be easy to use.

Problem: Easy to use is subjective and cannot be tested consistently Clarification question: Which users must complete which tasks, with what training, time limit and acceptable error rate?

Patient search should be fast.

Problem: Fast has no measurable response time, data size or operating condition. Clarification question: What maximum response time is acceptable, and for how many patient records?

The system should securely manage data.

Problem: Securely does not specify access rules, threats or controls. Clarification question: Who may view or change each type of data, and what authentication, logging and protection are required?

Appointments should normally be easy to cancel.

Problem: Normally and easy are vague; authorised users and cancellation rules are missing. Clarification question: Who may cancel an appointment, under what conditions, and what must happen to its status and history?

Activity 4 - AI Requirements Audit

Classify each suggestion: Confirmed / Assumption requiring validation / Unsupported / Out of scope.

AI suggestion	Classification	Evidence / reason
Patients receive SMS reminders.	Assumption requiring validation	The brief mentions appointments but does not request reminders or SMS integration.
Facial recognition login.	Unsupported	No authentication method or biometric requirement appears in the brief.
Receptionists create appointments.	Confirmed	The scenario identifies staff appointment work, and the required system manages appointments.
Online payment.	Out of scope	The brief concerns patients, practitioners and

		appointments, not billing or payments.
Practitioners view schedules.	Assumption requiring validation	Reasonable for appointment management, but the brief does not explicitly say practitioners use the system.
AI recommends treatments.	Out of scope	The system is administrative; clinical decision support is not mentioned
Cancelled appointments remain in history.	Assumption requiring validation	The brief identifies limited history but does not define cancellation retention rules.

Exit question

Why is 'AI suggested it' not sufficient evidence for a requirement?

'AI suggested it' is not sufficient evidence because AI can infer plausible features that the client never requested. A valid requirement needs traceable evidence, such as the client brief, a stakeholder statement, a law, a policy or an approved business rule.
